Why numerical relativity

Study of systems with strong and dynamical gravitational fields

- Gravitational radiation
 - Astrophysics, gravitational wave astronomy
- Mathematical and theoretical Physics:
 - Cosmic censorship
 - Instabilities (Black hole interior, Myers-Perry)
- High-energy particle systems:
 - AdS/CFT correspondence;
 - Black hole production at the LHC;

Gravitational waves

- Accelerated bodies emit gravitational radiation
- Detected **indirectly** by measurements of the Hulse-Taylor binary system (1993 Nobel Prize)
- Interact weakly with matter \Rightarrow carry unique information about astronomical phenomena
 - \Rightarrow New window to the universe
- Observations suggest we live in an approximately de Sitter Universe;
 - can we make numerical relativity in de Sitter?

Mathematical and theoretical Physics

- Cosmic censorship hypothesis:
 - does it hold under extreme conditions?
Sperhake, Cardoso, Pretorius, Berti, Gonzales, 2008
- No no-hair theorem for $D > 4 \Rightarrow$ black hole solutions with non-spherical topology.
 - (Non-)Linear stability of higher-dimensional black objects:
 - Myers-Perry black hole
 - Black ring
 - ...

Choptuik, Lehner, Olabarrieta, Petryk, Pretorius, Villegas, 2003
Shibata & Yoshino, 2010

Emparan & Reall, 2008

AdS/CFT duality

Issues with numerical simulations in AdS:

- AdS is not globally hyperbolic
- The boundary plays an active role

High-energy particle systems

- Large extra dimensions scenarios:
 - fundamental Planck scale could be as low as the TeV:
⇒ at the LHC particles collide at centre of mass energies above the fundamental Planck scale.
- *Matter does not matter*: for energies above Planck scale,
 $E = 2\gamma m_0 c^2 > E_{\text{Planck}}$
 - gravity is the dominant force;
 - internal structure of particle not important for understanding of process.

⇒ high energy particle collisions should be well described by black hole collisions – **classical** general relativity.

High-energy particle systems

- If quantum gravity scale is near the TeV:
 - ⇒ black hole production at the LHC
 - ⇒ evidences for extra dimensions

- High-energy collision of two black holes can model a high-energy collision of relativistic objects;
- Amount of collision energy lost in gravitational radiation as a function of space-time dimension;
- Need cross section for black hole production;

Black hole collisions in $D = 4$

- two black holes
 - Total rest mass: $M_0 = M_A + M_B$
 - Initial position: $\pm x_0$
 - Linear momentum: $\mp P[\cos \alpha, \sin \alpha, 0]$
- Impact parameter: $b \equiv \frac{L}{P}$

Head-on collisions: $b = 0$, $\vec{S} = 0$

- Total radiated energy: 14 ± 3 % for $v \rightarrow 1$
Sperhake *et al.* '08

- Agreement with approximative methods
e.g. Berti *et al.* '10

Zoom whirl orbits: $b \neq 0$

1-parameter family of initial data: impact parameter

Pretorius & Khurana '07

- Fine tune parameter
⇒ “Threshold of immediate merger”
- Reminiscent of “Critical Phenomena”

Recoil in grazing collisions

- 2 sequences merging: $b = 3.34 M$ scattering: $b = 3.25 M$
- $v_{\max,s} = 12\,200$ km/s
 $v_{\max,m} = 14\,900$ km/s
- Large recoils for merger and scattering!
- $v_{\max} \propto E_{\text{rad}}$

Axial symmetry $SO(D - 2)$ and $SO(D - 3)$

- Highly symmetric systems;
- Can be reduced to effective $3 + 1$ systems;
 ⇒ We can use existing numerical codes (with adaptations);

Formalism

Most general metric element

$$ds^2 = g_{\mu\nu} dx^\mu dx^\nu + e^{2\phi} d\Omega_{D-4}^2$$

$\mu = 0, 1, 2, 3.$

D -dimensional vacuum Einstein equations imply

$$e^{2\phi} ((D-4)\partial^\alpha\phi\partial_\alpha\phi + \nabla^\alpha\partial_\alpha\phi) = D-5$$

$$R_{\mu\nu} = (D-4)(\nabla_\nu\partial_\mu\phi + \partial_\mu\phi\partial_\nu\phi)$$

Formalism

The resulting system is

$$(\partial_t - \mathcal{L}_\beta) \gamma_{ij} = -2\alpha K_{ij},$$

$$(\partial_t - \mathcal{L}_\beta) K_{ij} = -D_i \partial_j \alpha + \alpha \left({}^{(3)}R_{ij} + K K_{ij} - 2K_{ik} K^k{}_j \right) \\ - \alpha (D - 4) (D_i \partial_j \phi - K_{ij} K_\phi + \partial_i \phi \partial_j \phi),$$

$$(\partial_t - \mathcal{L}_\beta) \phi = -\alpha K_\phi,$$

$$(\partial_t - \mathcal{L}_\beta) K_\phi = \alpha \left[(D - 5) e^{-2\phi} - (D - 4) \partial_i \phi \partial^i \phi - D^i \partial_i \phi \right. \\ \left. + (D - 4) K_\phi^2 + K K_\phi \right] - \partial^i \alpha \partial_i \phi,$$

→ effective 3 + 1 system with source terms

Formalism

The resulting system is

$$(\partial_t - \mathcal{L}_\beta) \gamma_{ij} = -2\alpha K_{ij},$$

$$(\partial_t - \mathcal{L}_\beta) K_{ij} = -D_i \partial_j \alpha + \alpha \left({}^{(3)}R_{ij} + K K_{ij} - 2K_{ik} K^k{}_j \right) \\ - \alpha (D - 4) (D_i \partial_j \phi - K_{ij} K_\phi + \partial_i \phi \partial_j \phi),$$

$$(\partial_t - \mathcal{L}_\beta) \phi = -\alpha K_\phi,$$

$$(\partial_t - \mathcal{L}_\beta) K_\phi = \alpha \left[(D - 5) e^{-2\phi} - (D - 4) \partial_i \phi \partial^i \phi - D^i \partial_i \phi \right. \\ \left. + (D - 4) K_\phi^2 + K K_\phi \right] - \partial^i \alpha \partial_i \phi,$$

→ effective 3 + 1 system with **source terms**

Formalism

Constraints

$$\mathcal{H} \equiv R + K^2 - K_{ij}K^{ij} - 16\pi E = 0$$

$$\mathcal{M}^i \equiv \nabla_j (K^{ij} - \gamma^{ij}K) - 8\pi p^i = 0$$

Electromagnetic analogy

Evolution equations

$$-\partial_t \vec{E} + \nabla \times \vec{H} = 4\pi \vec{j}$$

$$-\partial_t \vec{H} + \nabla \times \vec{E} = 0$$

Constraints

$$\nabla \cdot \vec{E} = 4\pi \rho$$

$$\nabla \cdot \vec{H} = 0$$

Initial data

Example: Brill-Lindquist initial data

$$ds^2 = \psi^{\frac{4}{D-3}} \left(dz^2 + d\rho^2 + \rho^2 d\xi^2 \right) + \psi^{\frac{4}{D-3}} \rho^2 \sin^2 \xi^2 d\Omega_{D-4}^2,$$

$$\psi = 1 + \frac{\mu_1}{4 \left[(z - z_1)^2 + \rho^2 \right]^{\frac{D-3}{2}}} + \frac{\mu_2}{4 \left[(z - z_2)^2 + \rho^2 \right]^{\frac{D-3}{2}}}$$

To match with

$$ds^2 = g_{\mu\nu} dx^\mu dx^\nu + e^{2\phi} d\Omega_{D-4}^2$$

Wave extraction

Generalization of Regge-Wheeler-Zerilli to higher-dimensions.

Kodama-Ishibashi formalism

$$g_{AB} = g_{AB}^{(0)} + h_{AB}$$

$$(ds^{(0)})^2 = - \left(1 - \frac{r_S^{D-3}}{r^{D-3}} \right) dt^2 + \left(1 - \frac{r_S^{D-3}}{r^{D-3}} \right)^{-1} dr^2 + r^2 d\Omega_{D-2}$$

Kodama & Ishibashi 2003

Decomposition of perturbation into harmonic functions:

- scalar harmonics, $\square S = -k^2 S$, $k^2 = l(l + D - 3)$
 - in $D = 4$: “polar” or even perturbation
- vector harmonics, $\square \mathcal{V}_k = -k_V^2 \mathcal{V}_k$
 - in $D = 4$: “axial” or odd perturbation
- tensor harmonics, $\square \mathcal{T}_{kl} = -k_T^2 \mathcal{T}_{kl}$
 - vanish in $D = 4$

Wave extraction

Emitted gravitational waves described by master function Φ

$$(\square - V)\Phi_l = 0$$

Energy flux

$$\frac{dE_l}{dt} = \frac{1}{32\pi} \frac{D-3}{D-2} k^2 (k^2 - D + 2) (\Phi'_{,t})^2$$
$$E = \sum_{l=2}^{\infty} \int_{-\infty}^{+\infty} dt \frac{dE_l}{dt}$$

Procedure

- 1 Compute master function Φ
- 2 \rightarrow Energy flux

Collision from rest

- Estimates for time it takes for BHs to collide in $D = 5$.

Wave forms

- $l = 2$ mode of $\Phi_{,t}$
 $d = 6.37 r_S$ (black)
 $d = 10.37 r_S$ (red)

characteristic ringdown frequency:

$$r_S \omega = 0.955 \pm 0.005 - i(0.255 \pm 0.005)$$

$$(r_S \omega = 0.9477 - i0.2561, \text{ e.g., Berti et al. 2009})$$

Radiated energy

D	$E^{\text{rad}}/M(\%)$
4	0.055
5	0.089

Black holes in de Sitter

- Two parameters: H , d
- Initial data: McVittie type binaries McVittie '33
- “Small BHs”: $d < d_{crit} \Rightarrow$ merger
 $d > d_{crit} \Rightarrow$ no common AH
- “Large” holes at small d : Cosmic Censorship holds

Conclusions

- 1 Numerically solving Einstein's equations in dynamical situations has the potential to answer important questions.
- 2 “3+1” numerical framework can be modified for higher D : head-on collision of non-spinning black holes in any dimension can be reduced to an effective $3 + 1$ system with matter.
- 3 Enables us to study higher-dimensional systems (with enough symmetry) using the existing numerical codes.
Stability not yet as robust as in $D = 4$
- 4 We successfully evolved a black hole collision (from rest) in a five-dimensional space-time.
- 5 BH in de Sitter
 - Evolved head-on collision of BHs in asymptotically de Sitter spacetime and monitored apparent horizons;
 - Studied formation of common apparent horizon as function of initial separation;

To do

- 1 Boosted black hole collisions in $D \geq 5$;
- 2 Collisions of spinning black holes;
- 3 Stability properties of higher dimensional black objects;
- 4 Collisions of charged BH; does charge play a role in high speed collisions?
